One factor that may determine whether or not a software application becomes successful is the time required for development, testing, and deployment. Typically, the time that it takes to develop software products increases with the complexity of the product. Even if a software application is designed to be simple, the process of designing and implementing the software can be a long and arduous process. In addition to the complexities of the code, bugs may be introduced in the code or in a product that relies upon the software. Testing the software for bugs and any dependencies of the software on other programs also adds to the time required for deployment. A large code base containing a number of software applications can be difficult to manage, debug, and maintain. To resolve the problems of managing, debugging, and maintaining software code, a number of solutions have been developed. For example, one solution that has been developed to manage software is the use of object-oriented programming. Object-oriented programming allows applications to be divided into “objects,” each of which can inherit from other objects. Objects may also be grouped into classes that, along with other objects, may be used in an application. Classes define the characteristics of the objects that they contain and object-oriented programming allows one object to be defined in terms of the classes of other objects. Software applications based upon object-oriented programming languages typically have object models that reflect the structure of the business domain of the application. For example, a software application may be based upon a business 2d92ce491b
